# Who makes up the Belgian Virgo group?

Universiteit  
Antwerpen

UCLouvain

- Joined Virgo in July 2018; group has grown to 16 members, many young people
- Weekly meetings, strong collaboration
- VUB has applied to join Virgo

UCLouvain

# Ongoing activities

- Broadband isotropic and directional stochastic gravitational wave searches
- Searches for (subsolar) primordial black hole mergers with CW and matched filter methods, and from a stochastic GW background
- Analysis of Schumann resonances
- Long gravitational wave transient (burst) searches
- Detecting binary systems before merger with deep learning
- Absolute calibration of the Virgo antenna
- Computing - CPUs and GPUs at UCLouvain center within the LIGO/Virgo computing infrastructure
- Instrumentation: mirror coating research, optics commissioning and development, Einstein Telescope preparation (mirror seismic isolation)
- Probing dark matter with gravitational wave detectors

- The mirrors move differently in response to passing GWs that induce a differential strain on the detector
- The phase  $\phi$  is measured:  $\phi = \frac{\Delta L}{L} = \int f(t)dt$

# Sources of gravitational waves

UCLouvain

■ Four major sources that LIGO/Virgo search for

UCLouvain

# Focus here on continuous waves

UCLouvain

Overview

Neutron stars

Dark matter  
around black  
holes

References

- Quasi-monochromatic, quasi-infinite duration
- Searches are computationally demanding: template searches difficult

UCLouvain

# Deformed neutron stars

- Small deformation and rotation  $\rightarrow$  gravitational waves (GWs)
- Rotate at  $\sim 10 - 1000$  Hz [10]
- Model:  $f = f_0 + \dot{f}(t - t_0)$  [4]
- $\dot{f}$ :  $[-1 \times 10^{-8}, 2 \times 10^{-9}]$  Hz/s
- Mechanisms of deformation
  - Crustal strain (starquake, formed at birth)
  - Strong *internal* magnetic field buried during accretion (MSPs) [8]

# Types of searches

UCLouvain

Overview

Neutron stars

Dark matter  
around black  
holes

References

Search type	Description	Sources
targeted	known $\alpha, \delta, f_0, \dot{f}$	Crab, Vela, MSPs
directed	known $\alpha, \delta$	galactic center
all-sky	nothing known	any

$\alpha$ : right ascension

$\delta$ : declination

$f_0$ : pulsar rotation frequency at a reference time  $t_0$

$\dot{f}$ : spindown

- Targeted/directed searches can be fully coherent
- All-sky searches are semicoherent: the Doppler shift causes  $O(10^{-4} f)$  Hz modulations and affects the Fast Fourier Transform time  $T_{FFT}$
- We “point” to specific locations when analyzing the data

UCLouvain

## Existing constraints from an all-sky search

- These are upper limits: the minimum deformation, or ellipticity  $\epsilon$ , we can see at 95% confidence
- $I_{zz} = 10^{38} \text{ kg} \cdot \text{m}^2$ , constraints possible on  $\frac{I_{zz}\epsilon}{d}$  [2]
- Deformations with smaller  $\epsilon$  are easier to form

# Prospects for LIGO/Virgo's next run (O3)

- All-sky search for isolated sources and sources in binary systems
- Known pulsars search
- Search for GWs from young supernova remnants

# The dark matter problem

- New particles and modifications to gravity have been proposed
- Dark matter can take many forms ( $10^{-22} - 10^{50}$  eV)
- GWs can probe nature of ultralight dark matter
  - A cloud of bosons can form around BHs and deplete its energy over time in the form of GWs

# Black hole (BH) superradiance

- Near a BH, quantum fluctuations  $\rightarrow$  bosons pop into existence
- Many bosons fall in, but if  $\lambda_c \sim R_{BH}$ , bosons can scatter off the BH
- Greater effect for BHs with higher spins  $\chi$
- Energy (mass/spin) extracted from the BH by scattering bosons  $\rightarrow$  outgoing boson amplitude boosted
- Unlike photons, bosons are massive, so they tend to be bound to the BH  $\rightarrow$  successive scatterings possible
- A boson “cloud” can form [7]
- Focus here is on scalar bosons, but clouds composed of vector/tensor bosons are possible [3]

# Growth of boson clouds

- Clouds are formulated as solutions to Schrodinger-like equations for a scalar field in the Kerr metric: “gravitational Hydrogen atom”
- The lowest, fastest growing state is  $l = 1, m = 1$

- Superradiance (instability) condition:  $\omega_{axion} < m\Omega_{BH}$
- No limit on the number of bosons in each state [6]

# Depletion of boson clouds

- Assume bosons couple to gravity and annihilate into gravitons [5]
- GWs are emitted from one energy level at a time  $\rightarrow$  monochromatic up to small spinup due to classical self-gravity
- Timescale of depletion  $\gg$  timescale of cloud growth
- Consider boson mass range  $[10^{-14}, 10^{-11}]$  eV

**We expect *continuous* gravitational waves!**

# Constraints from an all-sky search

- Reinterpretation of upper limits on  $\epsilon$  from slide 8:  $\epsilon \propto h_0$ , the GW amplitude [9]
- $h_0, f \rightarrow m_b$  and  $M_{BH}$  constraints with assumptions on BHs' spins  $\chi$ , distances  $d$ , and ages  $t_{age}$

- More combinations of  $m_b$  and  $M_{BH}$  excluded for younger systems (small  $t_{age}$ ) than older ones
- Darker colors are constraints on older systems

# Directed search for Cygnus X-1

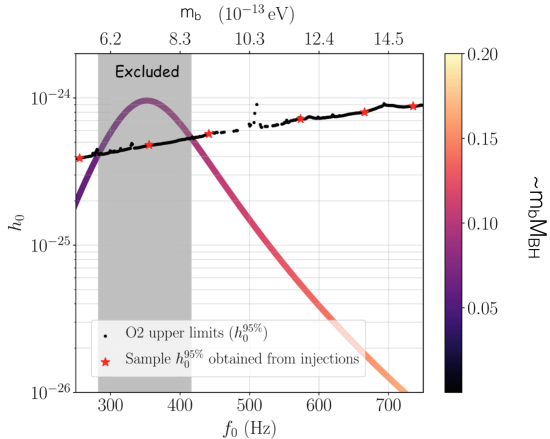

UCLouvain

Overview

Neutron stars

Dark matter  
around black  
holes

References

- Binary parameters and mass/spin known
- Viterbi method used to find the optimal signal path [11]

UCLouvain

# Prospects for the next observing run

- All-sky search for scalar boson clouds
- Directed search for vector boson clouds around binary systems
- Future detectors most likely needed to probe merger remnants
- Other probes of dark matter: dark photons directly interacting with the mirrors
  - Not GWs, but cause similar signatures
- This is new territory for CW analyses

Overview

Neutron stars

**Dark matter  
around black  
holes**

# Backup slides

# Existing constraints, targeted searches

UCLouvain

Overview

Neutron stars

Dark matter  
around black  
holes

References

- $I_{zz} = 10^{38} \text{ kg} \cdot \text{m}^2$ , constraints possible on  $I_{zz} \in [1]$
- The diagonal lines show the  $\epsilon$  that would be required if a star had a particular characteristic age  $\tau$  and was losing energy purely through GWs.

UCLouvain

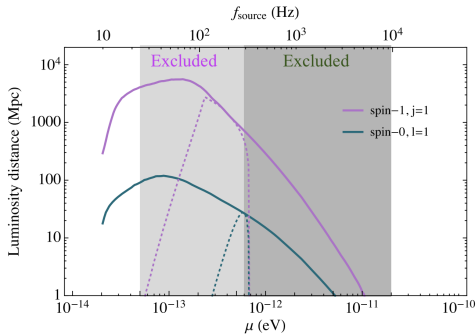

# Vector bosons

- Emit GWs with higher amplitudes, but on shorter timescales, than those from scalar bosons
- For shorter signals, spinup becomes important
- Parameter space mostly composed of “transient” continuous wave signals
- Possible targets: merger remnants, x-ray binaries
- Interplay between instability and depletion timescales important

# Distance reach

- Assumes monochromatic signal
- BH mass chosen as a function of particle mass to give the strongest GW signal
- Dotted line:  $M_{BH} = 64M_{sun}$

Ellipticity:

$$\epsilon \equiv \frac{|I_{xx} - I_{yy}|}{I_{zz}}, \quad (3.1)$$

Amplitude of CW:

$$h_0 = \frac{16\pi^2 G}{c^4} \frac{I_{zz} \epsilon f_{\text{rot}}^2}{d}, \quad (3.2)$$

Spindown limit:

$$h_{0,\text{sd}} = \frac{1}{d} \left( \frac{5GI_{zz}}{2c^3} \frac{|\dot{f}_{\text{rot}}|}{f_{\text{rot}}} \right)^{1/2}, \quad (3.3)$$
