Accelerator concept

Charged particles are accelerated, guided and confined by **electromagnetic fields**.

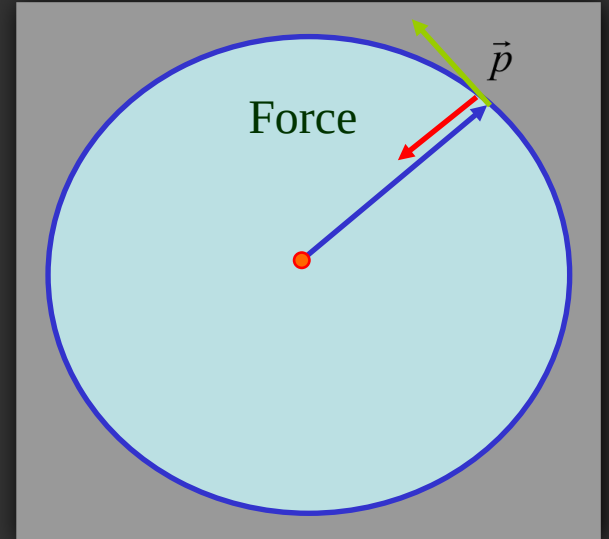

- Guiding: Dipole magnets
- Focusing: Quadrupole magnets
- Accelerating: RF cavities

Guiding with Dipole Magnets

Lorentz force $\vec{F} = e(\vec{v} \times \vec{B} + \vec{E})$

Circular Motion $F = \frac{m v^2}{r}$

Magnetic rigidity $B r = \frac{m v}{e} = \frac{p}{e}$

LHC: $r = 2.8$ km given by LEP tunnel!

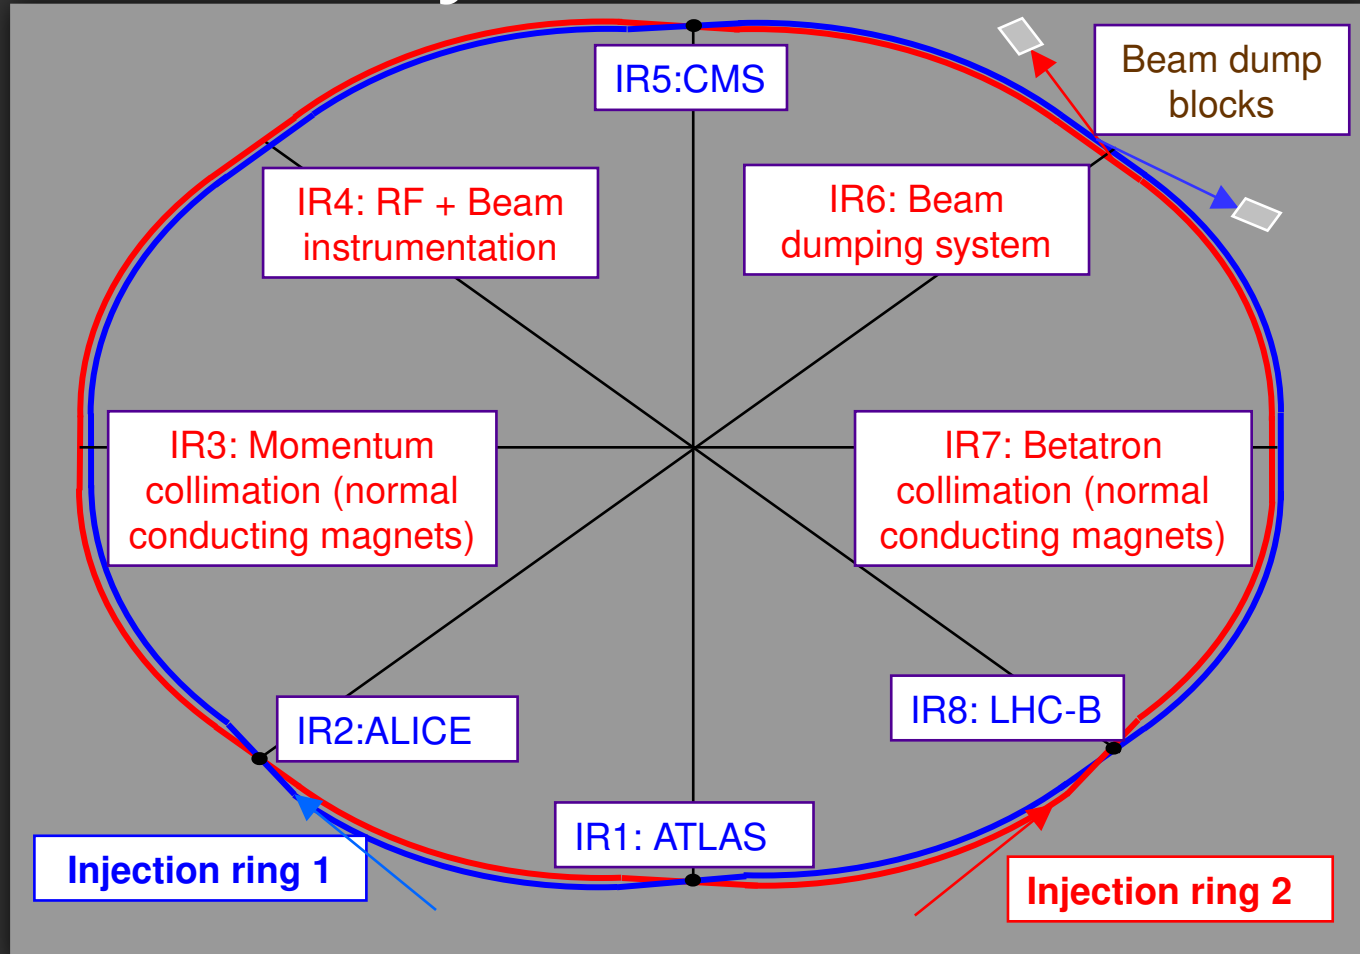

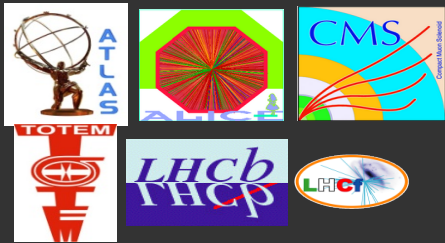

To reach $p = 7$ TeV/c with a bending radius of $r = 2805$ m:

Bending field : $B = 8.33$ Tesla

Two counter-rotating proton beams : beams in separate vacuum chambers with opposite B field direction.

LHC Layout

- 8 arcs.
- 8 long straight sections (insertions), ~ 700 m long.
- The beams exchange their positions (inside/outside) in 4 points to ensure that both rings have the same circumference !

J. Wenninger LNF Spring School, May 2010

Two-in one dipole magnet design

Coils for dipoles

Dipole length 15 m
 $I = 11\,800\text{ A @ } 8.3\text{ T}$

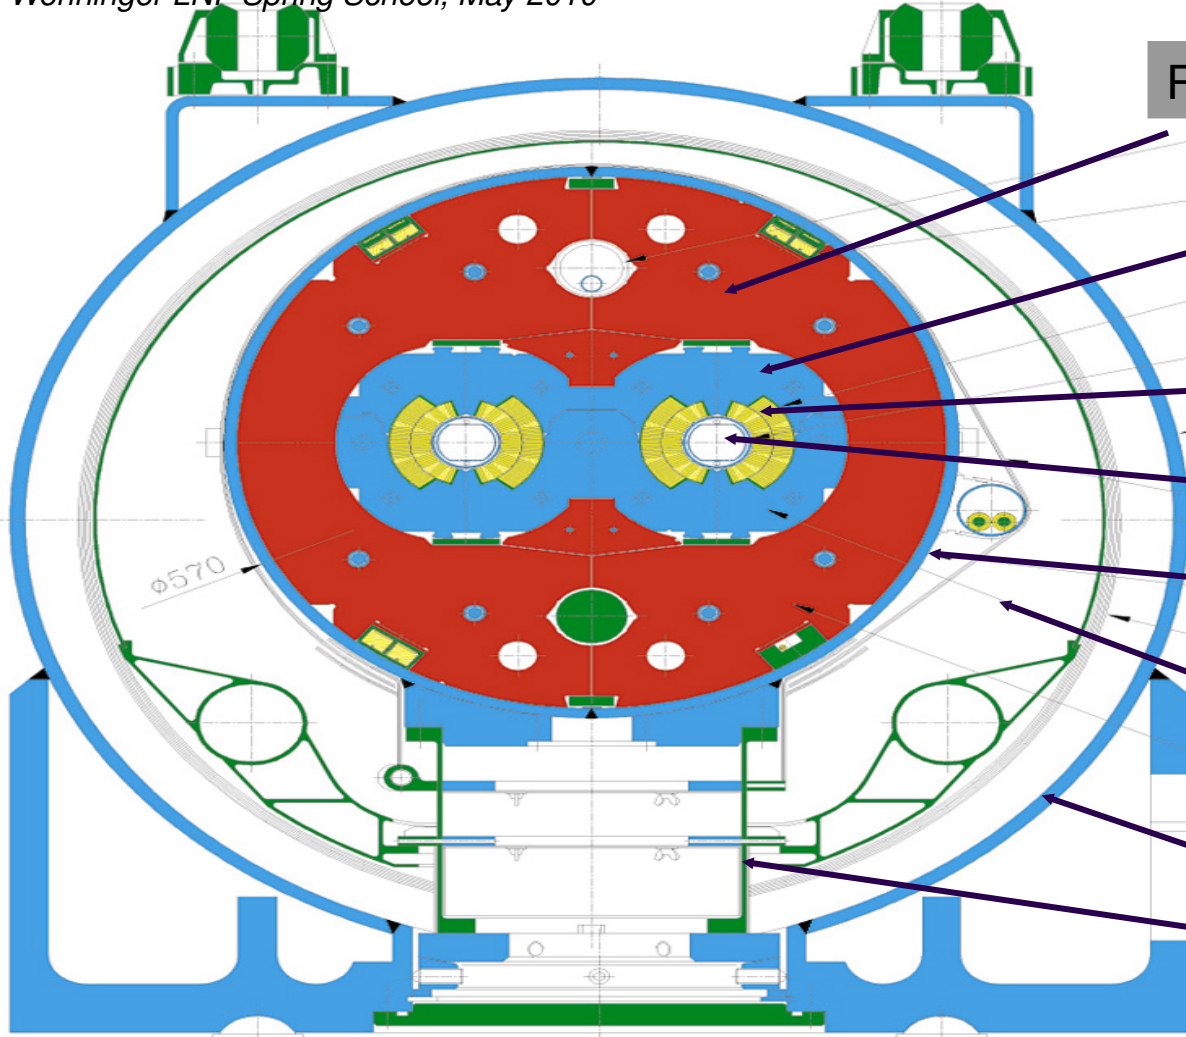

The coils must be aligned very precisely to ensure a good field quality (i.e. 'pure' dipole)

Superconductivity

- Stable dipole field of 8.3 Tesla can only be obtained with superconducting magnets !
- The material determines:
 - T_c** critical temperature
 - B_c** critical field
- The cable production determines:
 - J_c** critical current density
- Lower temperature → increased current density → higher fields.
- Typical for NbTi @ 4.2 K
2000 A/mm² @ 6T
- To reach 8-10 T, the temperature must be lowered to 1.9 K – superfluid Helium !

Ferromagnetic iron

Non-magnetic collars

Superconducting coil

Beam tube

Steel cylinder for Helium

Insulation vacuum

Vacuum tank

Supports

Weight (magnet + cryostat) ~ 30 tons, length 15 m

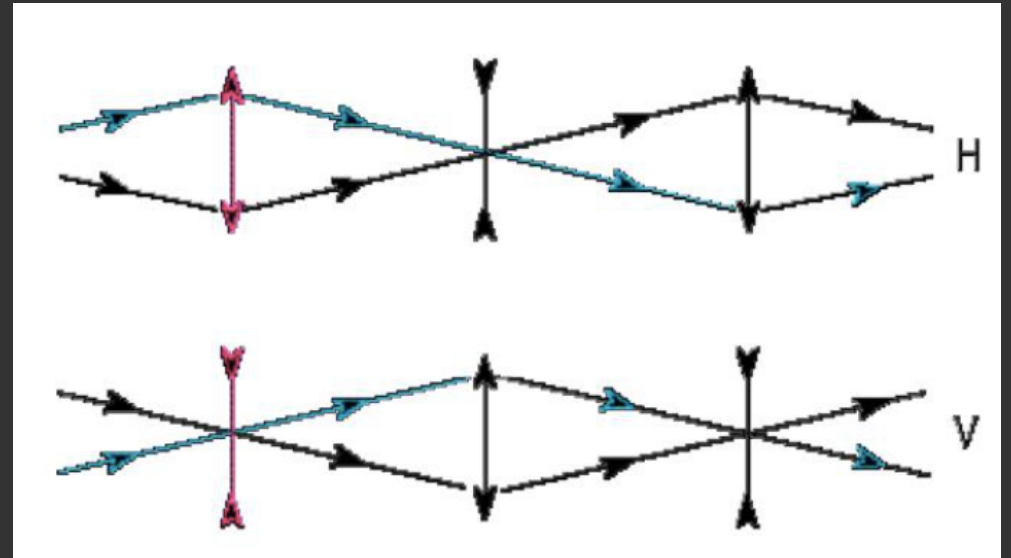

Focusing with Quadrupoles

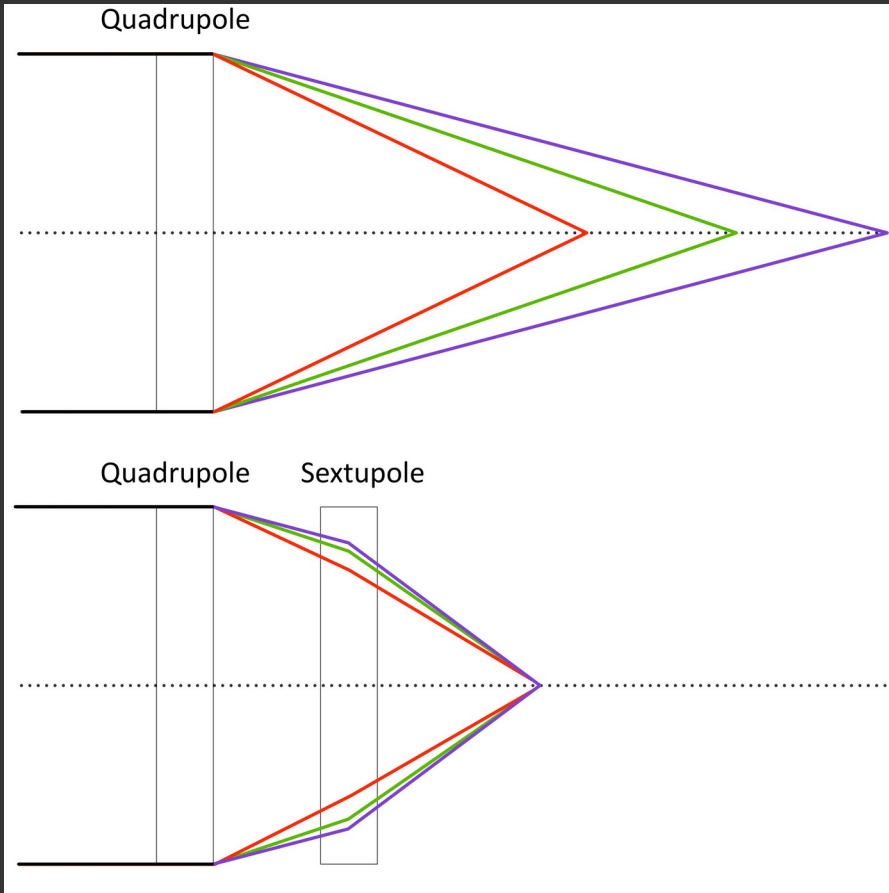

- Transverse focusing is achieved with **quadrupole magnets**, which act on the beam like an optical lens.
- Linear increase of the magnetic field along the axes (no effect on particles on axis).
Focusing in one plane, **de-focusing** in the other!

Alternating gradient lattice

- Dipoles keep particles on track
- Alternating Quadrupoles create net focussing in both planes.

Chromatic Correction with Sextupoles

- Particles with different energies react differently in quadrupole magnets → «Chromatic Aberration »
- Can be solved by Sextupoles magnets

Acceleration with RF cavities

Acceleration with electric field in Radio-Frequency cavities.

In circular accelerators, the acceleration is done with small steps at each turn.

LHC : acceleration from **450GeV** to **7 TeV** lasts ~ 20 minutes, with an average energy gain of ~ 0.5 MeV on each turn.

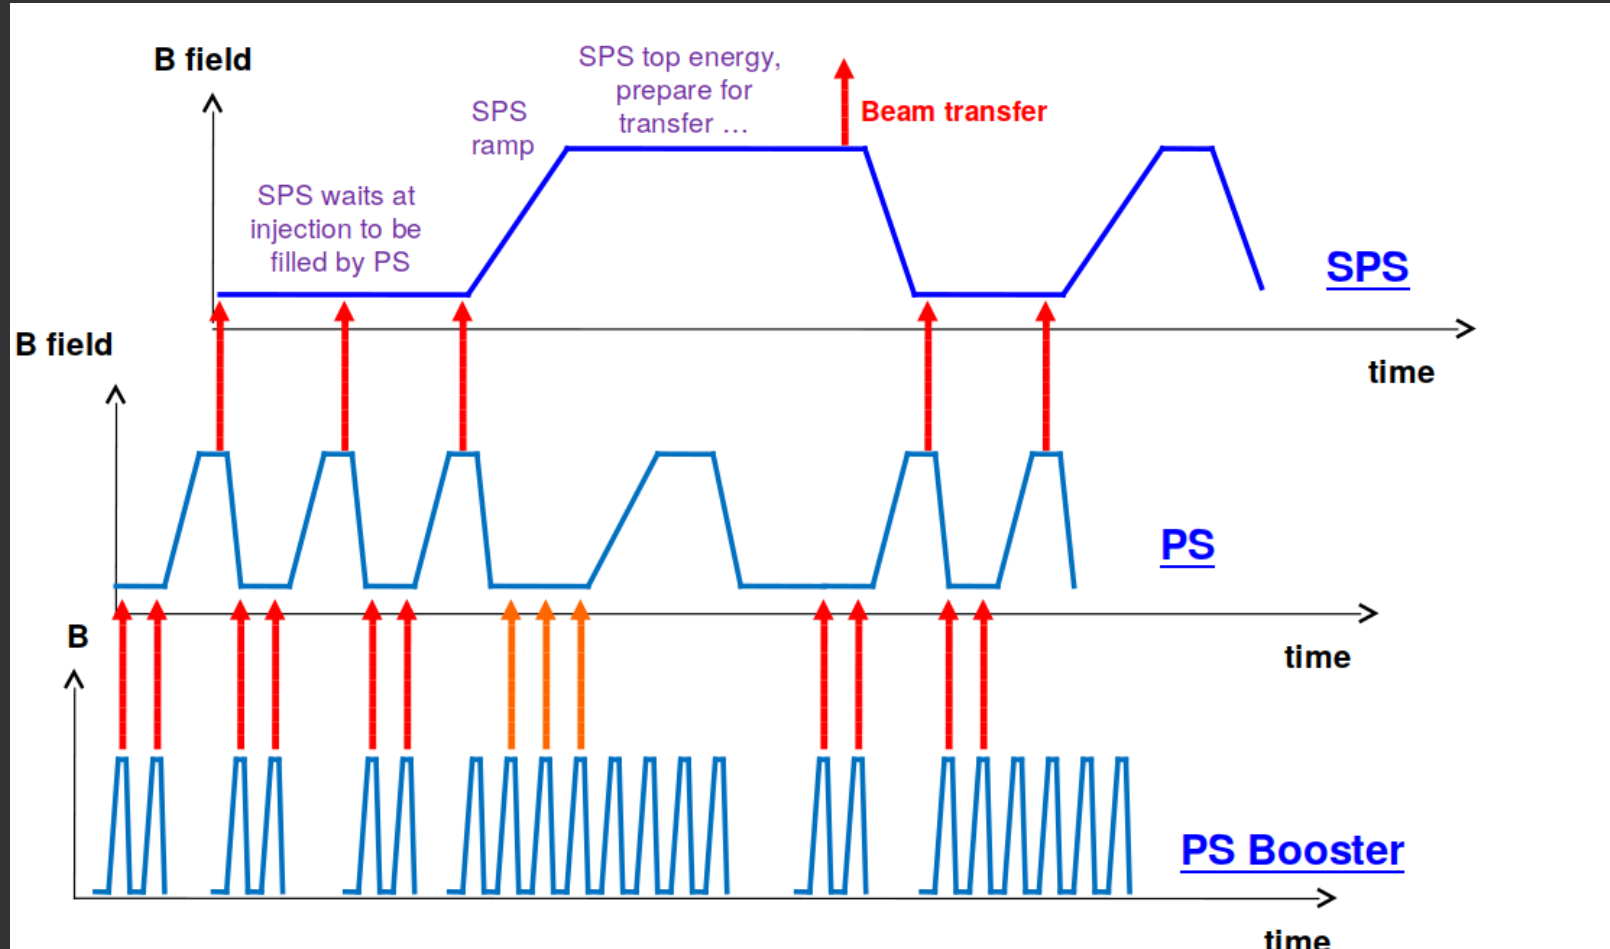

Combining the beams for collisions

- The 2 LHC beams must be brought together to collide.
- Over ~260 m, the beams circulate in the same vacuum chamber.

Principle of injector cycling

SM18 : CERN Magnet testing facility

Destructive power of an uncontrolled quench

LHC dipole of 15m and 8.35T stores 8 MJ, which corresponds to melting 1.5L of copper, enough to evaporate 10cm of coil !

And we have seen in Sep 2008 what a few magnet quenches can do!

<https://www.youtube.com/watch?v=J27W0e0c0k0>

ATLAS detector toroid stores 1.6 GJ, good for 600L of melted copper, or equivalent to the collision energy of 100 trucks of 40 tons with speed of 100 km/h!

To be safe with equipment and personnel, Quench Protection has to cover all possible quenches in the entire electrical circuit from + to - terminal on the cryostat (current leads & bus connections & coil)

Damage at an LHC interconnect
